### A\* SEARCH ALGORITHM

A heuristic algorithm sacrifices optimality, with precision and accuracy for speed, to solve problems faster and more efficiently.

All graphs have different nodes or points which the algorithm has to take, to reach the final node. The paths between these nodes all have a numerical value, which is considered as the weight of the path. The total of all paths transverse gives you the cost of that route.

Initially, the Algorithm calculates the cost to all its immediate neighboring nodes,  $n$ , and chooses the one incurring the least cost. This process repeats until no new nodes can be chosen and all paths have been traversed. Then, you should consider the best path among them. If  $f(n)$  represents the final cost, then it can be denoted as :

$f(n) = g(n) + h(n)$ , where :

$g(n)$  = cost of traversing from one node to another. This will vary from node to node

$h(n)$  = heuristic approximation of the node's value. This is not a real value but an approximation cost.

### AIM:

To implement an A\* search algorithm using Python.

### SOURCE CODE:

```
from collections import deque
```

```
class Graph:
```

```
    def __init__(self, adjac_lis):  
        self.adjac_lis = adjac_lis
```

```
    def get_neighbors(self, v):
```

```

        return self.adjac_lis[v]

def h(self, n):
    H = {
        'A': 1,
        'B': 1,
        'C': 1,
        'D': 1
    }
    return H[n]

def a_star_algorithm(self, start, stop):
    open_lst = set([start])
    closed_lst = set([])
    poo = {}
    poo[start] = 0
    par = {}
    par[start] = start

    while len(open_lst) > 0:
        n = None
        for v in open_lst:
            if n == None or poo[v] + self.h(v) < poo[n] + self.h(n):
                n = v;

        if n == None:
            print('Path does not exist!')
            return None

        if n == stop:
            reconst_path = []

            while par[n] != n:
                reconst_path.append(n)
                n = par[n]

            reconst_path.append(start)

            reconst_path.reverse()

            print('Path found: {}'.format(reconst_path))
            return reconst_path

```

```

for (m, weight) in self.get_neighbors(n):
    # if the current node is not present in both open_lst and closed_lst
    if m not in open_lst and m not in closed_lst:
        open_lst.add(m)
        par[m] = n
        poo[m] = poo[n] + weight
    else:
        if poo[m] > poo[n] + weight:
            poo[m] = poo[n] + weight
            par[m] = n

        if m in closed_lst:
            closed_lst.remove(m)
            open_lst.add(m)
    open_lst.remove(n)
    closed_lst.add(n)

print('Path does not exist!')
return None

adjac_lis = {
    'A': [('B', 1), ('C', 3), ('D', 7)],
    'B': [('D', 5)],
    'C': [('D', 12)]
}
graph1 = Graph(adjac_lis)
graph1.a_star_algorithm('A', 'D')

```

## **OUTPUT:**

A screenshot of a Jupyter Notebook interface. The top bar shows the file name '220701039.ipynb' and a star icon. Below the bar is a menu with 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. The main area has a toolbar with '+ Code' and '+ Text' buttons. The code cell contains two lines: `graph1 = Graph(adjac_lis)` and `graph1.a_star_algorithm('A', 'D')`. The output cell shows the result: `Path found: ['A', 'B', 'D']` and `['A', 'B', 'D']`. The right sidebar shows 'RAM' and 'Disk' usage, a 'Gemini' button, and a 'Share' button.

```
graph1 = Graph(adjac_lis)
graph1.a_star_algorithm('A', 'D')
```

Path found: ['A', 'B', 'D']  
['A', 'B', 'D']

## **RESULT :**
